

REMEDICATION METHOD OF MEDIA  
AND IRON POWDER FOR DEHALOGENATION  
OF HYDROGENATED HYDROCARBONS

5 BACKGROUND OF THE INVENTION

1. Field of the Invention

[0001] The invention relates to a method for decontaminating halogenated hydrocarbons toxic to humans by eliminating halogens from the halogenated hydrocarbons. More specifically, the invention relates to a method for decontaminating the halogenated hydrocarbons contained in polluted media such as soil, water and/or gas by dehalogenation, and an iron powder for dehalogenation of the halogenated hydrocarbons (referred to as an environment remediation iron powder, or simply as a remediation iron powder).

2. Description of the Related Art

[0002] The remediation method for the soil and ground water polluted with the halogenated hydrocarbons harmful to humans is categorized as (1) a method for treating the polluted soil and ground water while maintaining their current situations (an in situ treatment), (2) a method for treating gases in the polluted soil or polluted ground water after pumping from the ground (treatment after in situ extraction) and (3) a method for treating the polluted soil after excavation (excavation treatment).

[0003] A method using an iron powder as a reductant for decontamination of harmful halogenated hydrocarbons by

dehalogenation has been proposed. For example, Japanese Unexamined Patent Application Publication No. 10-263522 proposes a remediation method of soil and soil moisture by forming an iron powder dispersion layer in the soil followed by allowing ground water to contact the layer for decontamination of the halogenated hydrocarbons. Japanese Unexamined Patent Application Publication No. 11-235577 also proposes a remediation method of soil by adding the iron powder to and mixing with the soil (excavated or not) for decontaminating the soil by dehalogenation.

[0004] The patent publication cited above (Japanese Unexamined Patent Application Publication No. 10-263522) describes that reductive power of the iron powder is reduced by forming iron oxide on the surface of the iron particles by a reaction with oxygen in the soil. As a counter measure of this problem, the patent publication also proposes deoxygenation of the soil in the vicinity of the iron powder by allowing a reductive substance to disperse in the soil. This means that persistence of the reductive power of the iron powder is a problem in the former patent publication.

[0005] The method described in the latter patent publication (Japanese Unexamined Patent Application Publication No. 11-235577) proposes an iron powder containing 0.1% by mass or more of carbon and having a specific surface area of 500 cm<sup>2</sup>/g or more, wherein the iron powder comprises sponge like particles having a pearlite texture as a structure with a particle size distribution that allows 50% or more of the total powder to pass through a 150

µm sieve.

[0006] However, dehalogenation ability of the iron powder disclosed in that patent publication is not always sufficient and it appears that the component of the iron powder is not optimized.

5 [0007] An iron powder containing 0.020 to 0.5% by weight of phosphorous, sulfur or boron has been proposed for efficiently removing phosphor compounds in drainage (Japanese Unexamined Patent Publication No. 2000-80401). According to the patent publication, iron powder is rapidly dissolved in the drainage due  
10 to selected trace elements in the iron powder, and has a high decontamination ability of phosphorous compounds. The objective effect thereof is to accelerate decontamination of phosphor in the drainage by increasing the dissolving speed of iron.

[0008] According to the mechanism of the iron powder disclosed  
15 in the foregoing patent publication, a compound which hardly dissolves and has a small solubility product constant such as iron phosphate is formed between the dissolved iron and phosphor in the drainage to remove phosphor in the drainage by precipitation. This technology is fundamentally different from the technology  
20 for reductive decomposition of harmful substances on the surface of iron according to this invention.

[0009] The patent publication cited above describes that the iron powder can efficiently remove other harmful substances such  
as heavy metals and chlorinated organic compounds as well.

25 However, the removal mechanism of other respective harmful substances are not explained. That patent publication assumes

the same mechanism for removal of the phosphorous compounds, or only exemplifies as one of general uses of the iron powder.

[0010] Further, no applications to the soil and/or groundwater are described in the patent publication cited above.

- 5 [0011] Another patent publication proposes an iron powder containing 0.1 to 10% by mass of copper for removing the halogenated hydrocarbons in the soil and/or groundwater (Japanese Unexamined Patent Application Publication No. 2000-5740). However, copper itself is a harmful metal with a danger of  
10 secondary pollution.

#### OBJECT OF THE INVENTION

- [0012] Polluted groundwater may bring about far more crucial damage over surface drainage, since identification of pollution sources is usually difficult in the polluted groundwater as  
15 compared to polluted surface drainage. Accordingly, prompt decontamination of the polluted groundwater has been urgently required. Persistence of the activity of the iron powder as a reductant is also strongly required for using the iron powder because the iron powder cannot be frequently replaced.

- 20 [0013] The halogenated hydrocarbon may also be present as a gas in the polluted soil and air different from the halogenated hydrocarbons in the drainage and groundwater. Therefore, it is advantageous to establish a method for efficiently decontaminating halogenated hydrocarbons in the gas for  
25 remediation of the polluted soil and air.

[0014] Accordingly, it is an object of the invention to provide

a method for rapidly decomposing the halogenated hydrocarbons in polluted media such as soil, water (groundwater) and/or gas by dehalogenation, and an iron powder suitable for dehalogenation.

## 5 SUMMARY OF THE INVENTION

10045316-110701  
10 [0015] The invention provides a remediation method of media including soil, water and/or gases by dehalogenation of halogenated hydrocarbons by contacting halogenated hydrocarbons contained at least in one of the media, soil, water and/or gases with an iron powder containing about 0.03 to about 2% by mass of sulfur.

[0016] Preferably, the iron powder contains about 0.1% by mass or less of manganese.

15 [0017] Preferably, precipitates of sulfur are exposed on the surface of the iron powder. The amount (or numbers) of the precipitated sulfur on the surface is preferably assessed by the amount of Fe-S based compounds existing on the surface.

[0018] The invention also provides an iron powder for dehalogenation of halogenated hydrocarbons containing about 0.03  
20 to about 2% by mass of sulfur.

[0019] Preferably, the iron powder for dehalogenation of halogenated hydrocarbons contains about 0.1% by mass or less of manganese.

25 [0020] Preferably, the iron powder for dehalogenation of halogenated hydrocarbons comprises precipitates of sulfur exposed on the surface of the iron powder. The amount of the

precipitated sulfur on the surface is also preferably assessed by the amount (or numbers) of Fe-S based compounds present (precipitated) on the surface.

[0021] The iron powder as hitherto described is preferably  
5 manufactured by a water atomization method. The iron powder manufactured by the water atomization method may be directly used, or an iron powder obtained by finish reduction of the iron powder manufactured by the water atomizing method may be used depending on the application fields.

#### BRIEF DESCRIPTION OF THE DRAWINGS

[0022] Fig. 1 shows a SEM photograph (with a magnification of 500) of the surface of the atomized iron powder (an iron powder obtained by finish reduction of a water atomization iron powder  
15 containing 0.4% by mass of sulfur and 0.05% by mass of manganese) according to the invention;

Fig. 2 shows the result of analysis (EBS image with a magnification of 500) of sulfur on the surface of the atomized iron powder shown in Fig. 1 by EPMA;

20 Fig. 3 shows the result of analysis (EBS image with a magnification of 500) of manganese on the surface of the atomized iron powder shown in Fig. 1 by EPMA;

Fig. 4 shows the result of analysis (EBS image with a magnification of 500) of iron on the surface of the atomized iron powder shown  
25 in Fig. 1 by EPMA;

Fig. 5 shows a SEM photograph (with a magnification of 500) of

the atomized iron powder (an iron powder obtained by finish reduction of a water atomization iron powder containing 0.4% by mass of sulfur and 0.5% by mass of manganese) in another embodiment of the invention;

5 Fig. 6 shows the result of analysis (EBS image with a magnification of 500) of sulfur on the surface of the atomized iron powder shown in Fig. 5 by EPMA;

Fig. 7 shows the result of analysis (EBS image with a magnification of 500) of manganese on the surface of the atomized iron powder shown in Fig. 5 by EPMA; and

Fig. 8 shows the result of analysis (EBS image with a magnification of 500) of iron on the surface of the atomized iron powder shown in Fig. 5 by EPMA.

## 15 DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0023] We have discovered the decontamination of harmful halogenated hydrocarbons is accelerated by dehalogenation (reduction) by contact with iron powder containing an appropriate amount of sulfur in iron powder particles. Although the reason why addition of sulfur is effective has not been made clear yet, we believe that inorganic compounds mainly comprising sulfur (iron compounds of sulfur) precipitated in the iron powder also precipitates on the surface of the iron powder, and a local cell reaction is enhanced by allowing the surface precipitation site to function as a local cathode.

[0024] In the local cell reaction as used herein, anodes and

10045316-110701  
cathodes are formed on the surface of the iron powder, and  
oxidation of iron takes place at the anode while reduction of the  
harmful halogenated hydrocarbons proceeds at the cathode. Since  
organic compounds are formed causing reductive dehalogenation,  
5 we believe that the polluted media, soil, water (groundwater) and  
gas (air) are decontaminated or remediated when the halogenated  
hydrocarbons are thought to be harmful.

[0025] The halogenated hydrocarbons are those containing  
halogens such as chlorine and bromine bound to the hydrocarbon  
10 molecule. While they mainly comprise volatile halogenated  
hydrocarbons such as trichloroethylene (abbreviate as TCE),  
tetrachloro-ethylene, 1,1,1-trichloroethane, 1,1,2-  
trichloroethane, 1,1-dichloroethylene, cis-1,2-  
dichloroethylene, trans-1,2-dichloroethylene, 1,1-  
15 dichloroethane, dichloromethane, carbon tetrachloride, methyl  
chloride, chloroform, methyl chloroform, 1,1,2,2-  
tetrachloroethane, 1,2-dichloropropane, 1,3-dichloropropane,  
methyl bromide, 2-bromopropane, 1,3-dibromopropane, 1,4-  
dibromopropane and allyl bromide, PCB and dioxin, or so, may be  
20 also be subject to the method of the invention.

[0026] Halogenated hydrocarbons typically leak from tanks and  
drainage, permeate into the soil and reside there. A part of the  
halogenated hydrocarbons are dissolved in the moisture in the soil  
and groundwater in a small concentration, while a part of the  
25 remaining halogenated hydrocarbons are gasified in the air.

[0027] The halogenated hydrocarbons are reduced with the iron

powder and converted into harmless non-halogen compounds. For example, TCE receives electrons (reduced) on the surface of the iron powder to form unstable intermediate compounds such as chloroacetylene by beta-elimination, and the intermediate compounds are finally decomposed to acetylene containing no chlorine atoms. Although reduction may proceed further, harmful compounds are converted into harmless compounds in any case by initiation by reception of electrons (reduction) on the surface of the iron powder.

10 [0028] Since sulfur in the iron powder is an element to deteriorate corrosion resistance, its content is usually restricted within a range of less than 0.03% by mass of the iron powder. However, the iron powder to be used in the invention contains about 0.03 to about 2% by mass of sulfur that is a larger content than usual. The preferable sulfur content is in the range of about 0.1 to about 1.0% by mass.

15 [0029] When the sulfur content is less than about 0.03% by mass, a local cell reaction by precipitated sulfur compounds is insufficient to initiate a dehalogenation reaction from being sufficiently promoted. When the sulfur content exceeds about 2% by mass, on the other hand, reactivity of the dehalogenation reaction decreases.

20 [0030] Since an iron powder containing a large quantity of sulfur is used in the invention, substantial quantities of sulfur are precipitated on the surface of the iron powder in a process of making or preparing iron powder such as a water atomization.

Consequently, the local cell reaction is enhanced by using the iron powder for remediation, thereby accelerating dehalogenation. It is desirable from the results of investigations to be described hereinafter that the configuration of sulfur precipitated on the surface is Fe-S based compounds.

[0031] Although the iron powder usually contains about 0.2% by mass or more of manganese, the manganese content of the iron powder to be used in the invention preferably contains about 0.1% by mass or less, more preferably about 0.06% by mass or less, of manganese.

The dehalogenation accelerating effect as a result of the large content of sulfur tends to be weakened when the manganese content is larger than the upper limit of the content above. We believe that the Mn-S based compounds formed by the reaction of manganese with sulfur has an inferior ability to accelerate the dehalogenation reaction.

[0032] The surface state of the iron powder for use in dehalogenation according to the invention will be described hereinafter by means of a scanning electron microscope (SEM) photograph in place of a drawing.

[0033] Fig. 1 shows the scanning electron microscope (SEM) photograph of the surface of the iron powder after a water atomization iron powder containing 0.4% by mass of sulfur and 0.05% by mass of manganese is subjected to a reduction treatment at 700°C for 1 hour in a hydrogen stream. Figs. 2 to 4 show assay results (EBS images) with an electron microanalyzer (EPMA) of sulfur, manganese and iron in the corresponding field of vision.

[0034] Similarly, Fig. 5 shows the scanning electron microscope (SEM) photograph of the surface of the iron powder after a water atomization iron powder containing 0.4% by mass of sulfur and 0.5% by mass of manganese is subjected to a reduction treatment at 700°C for 1 hour in a hydrogen stream. Figs. 6 to 8 show EBS images of sulfur, manganese and iron in the corresponding field of vision.

[0035] The magnification of the photographs in Figs. 1 to 8 is 500, and the scale at right-bottom of each field of vision denotes a length of 20  $\mu\text{m}$ .

10 [0036] Manganese is not precipitated on the surface as shown in Figs. 2 to 4 when the iron powder contains 0.05% by mass of manganese. Sulfur precipitated on the surface is believed to mainly comprise the Fe-S based compound.

15 [0037] When the iron powder contains 0.5% by mass of manganese, on the other hand, the precipitation site of sulfur approximately coincides with the precipitation site of manganese as shown in Figs. 6 to 8. This may suggest that sulfur is precipitated as a Mn-S based compound.

20 [0038] A difference may be observed between the reactivity of the local cells formed by the precipitated Fe-S based compound and Mn-S based compound, respectively, on the surface of the iron powder, since electrical conductivity of the former compound is largely different from the electrical conductivity of the latter compound. Actually, the difference is on the order of five digits as determined by the comparison between pure compounds of them.

25 In other words, FeS has an electrical resistivity of  $6 \times 10^{-6} \Omega\cdot\text{m}$

while MnS has an electrical resistivity of  $1 \times 10^{-1} \Omega \cdot m$ . Therefore, the Fe-S compound having a higher conductivity has a very large local cell forming ability when it is precipitated on the surface as compared with the Mn-S compound precipitated on the surface.

- 5 Accordingly, the Fe-S compound may have a quite large dehalogenation promoting effect.

[0039] The manganese content is preferably suppressed to be as small as possible since dehalogenation of the halogenated hydrocarbons is accelerated as the manganese content is decreased  
10 in the iron powder containing a large quantity of sulfur according to the invention.

[0040] There are no hindrances in acceleration of dehalogenation in the iron powder according to the invention, even when a small amount of other components (impurities) are contained.  
15 While representative impurities are about 0.005 to about 0.2% by mass of carbon, about 0.005 to about 0.30% by mass of silicon, about 0.005 to about 0.9% by mass of oxygen and about 0.005 to about 0.05% by mass of phosphorous, the contents are not restricted thereto. Other inevitable impurities, about the amount in  
20 commercial iron powders, may also be contained.

[0041] The iron powder according to the invention is preferably manufactured by water atomization of molten steel containing a considerable amount of sulfur. An iron powder whose surface oxidation film formed by atomization is reduced, for example, in  
25 a dry hydrogen stream may be used. Cutting debris of a free-machining steel containing a high concentration of sulfur may be .

also used.

[0042] The suitable mean particle diameter of the iron powder according to the invention differs depending on the application fields. A too fine iron powder is not preferable from the view  
5 point of prevention of clogging, when the iron powder is filled within a permeable wall for remediation of polluted groundwater. An iron powder having a particle size distribution in which about 50% by mass or more of the iron powder cannot pass through a 150  $\mu\text{m}$  sieve is preferably used.

10 [0043] An iron powder having a particle size distribution in which about 50% by mass or more of the iron powder can pass through a 150  $\mu\text{m}$  sieve is preferably used in the application for mixing the iron powder with a soil in the zone of aeration or excavated soil.

15 [0044] The iron powder according to the invention may be applied to various media including polluted soil, water such as groundwater, and gases such as air by methods known in the art. For example, the iron powder is allowed to contact the halogenated hydrocarbons by spraying or mixing, or by injection of the iron  
20 powder or a slurry of the iron powder, for remediation of polluted soil and/or polluted groundwater. When referring to "media" and/or "soil", these terms are intended to apply broadly to include excavated or unexcavated soil, municipal, refinery or chemical sludges or particulates, waterway and lagoon sediments and the  
25 like.

[0045] The moisture content of the soil is preferably about 40%

by mass or more. A reduction accelerating agent may be used together with the iron powder.

[0046] When the iron powder is applied for excavated polluted soil, the iron powder may be also allowed to contact the  
5 halogenated hydrocarbons by spraying or mixing, or by injection of the iron powder or a slurry of the iron powder, considering the moisture content, soil quality and soil pressure.

[0047] It is preferable that the soil is previously crushed to have a small diameter to allow the soil to contact the iron powder,  
10 when the excavated soil is viscous and has a large particle diameter. Groundwater may be allowed to passed through a permeable layer in the ground in which the iron powder has been added.

[0048] The amount of the iron powder used relative to the amount  
15 of the soil and groundwater is appropriately determined depending on the type of decontamination or the degree of pollution of the polluted soil.

[0049] (1) When the polluted soil and ground water is treated in situ, usually about 0.1 to about 10% by mass, preferably about  
20 0.5 to about 5% by mass, of the iron powder may be used relative to the object (soil and the like) to be remedied.

[0050] (2) When polluted groundwater is pumped (extracted) for remediation, usually about 0.1 to about 10% by mass, preferably about 0.5 to about 5% by mass, of the iron powder may be used  
25 relative to the polluted groundwater.

[0051] (3) When the polluted soil is treated by excavation,

usually about 0.1 to about 10% by mass, preferably about 0.5 to about 5% by mass, of the iron powder is used.

5 [0052] Since the iron powder is harmless, it is of no particular problem to leave it in the soil and groundwater upon completion of dehalogenation.

10 [0053] When the iron powder is applied for polluted air, the air may be allowed to flow through a vessel filled with the iron powder to permit the air to contact the iron powder. While the surface of the iron powder is required to be wet, adsorbed water is sufficient. One or more layers of water molecule layers are preferably formed on the surface of the iron powder.

[0054] Relative humidity of the air or atmosphere is preferably about 50% or more. Fillers and a reduction accelerating agent may be filled in the vessel in addition to the iron powder.

15 Examples

(Manufacture of iron powder)

20 [0055] A molten steel whose composition which had been adjusted by adding sulfur was melted by heating at 1700°C. After atomizing at a hydraulic pressure of 1177 MPa with water, the iron powder was sequentially dehydrated, dried, crushed (ground) and sieved. The iron powder after passing through a 180  $\mu\text{m}$  sieve was used for the dehalogenation experiments to be described hereinafter.

[0056] The water atomized iron powder was independently subjected to finish reduction in a hydrogen atmosphere at 900°C for 1 hour. A water atomized iron powder with finish reduction was prepared by sieving through a 180  $\mu\text{m}$  sieve after crushing the

raw iron powder to employ it in the dehalogenation experiments to be described hereinafter. The iron powder was decarbonized and annealed during the finish reduction.

[0057] Sulfur, manganese, carbon, silicon, phosphorous and oxygen contained in the water atomized iron powder and water atomized iron powder with finish reduction were analyzed according to JIS G1215, G1257, G1211, G1258, G1258 and Z2613, respectively. The content of each component in the iron powders used for the experiments is listed in Table 1.

10 [0058] The degree of precipitation of the sulfur compound on the surface of the iron powder was measured by the following procedure.

[0059] (1) Ten iron powder particles with a size that can accommodate one particle in one field of vision (with a magnification of 500) were selected from the iron powder samples, and a SEM photograph and EBS images of S and Mn were taken from the same field of vision using EPMA with a magnification of 500.

[0060] (2) The number (N) of the sulfur precipitate particles was counted in a field of vision of  $50\ \mu\text{m} \times 50\ \mu\text{m}$ , and the value of N was defined to be the degree of precipitation of the sulfur compound on the surface (in a unit of number of particles/ $250\ \mu\text{m}^2$ ) effective for dehalogenation. The particle overlapping the manganese precipitate was considered to be a Mn-S based compound, and was excluded from the count of the N value.

25 [0061] The degree of precipitation obtained (corresponds to the degree of precipitation of the Fe-S based compound) is listed in

Table 1.

(Dehalogenation)

5 [0062] Both the water atomized iron powder and water atomized iron powder with finish reduction used for dehalogenation had a specific surface area of 0.01 to 0.2 m<sup>2</sup>/g as determined by the BET method.

10 [0063] In 100 ml each of five glass vials, 50 ml of an aqueous solutions containing calcium carbonate with a concentration of 40 mg/L (liter), sodium bisulfate with a concentration of 80 mg/L and trichloroethylene (TCE) with a concentration of 5 mg/L was added followed by adding 5 g of the iron powder (water atomized iron powder or water atomized iron powder with finish reduction). Each vial was then sealed with butyl rubber with a fluorinated resin sheet and an aluminum cap. The sealed sample was shaken in the vertical axis direction of the vial at a rotational speed of 180 rpm in a constant temperature chamber controlled at 23 ± 2°C. The concentration of the TCE gas stored in the head space of each vial was analyzed with a gas detector tube at a predetermined time interval after initiation of shaking to measure the concentration of TCE in water. The vial once opened was not used for the analysis thereafter. The predetermined time intervals were one day, three days, five days, seven days, and ten days, respectively.

(Dehalogenation speed of TCE)

25 [0064] The TCE concentration in water was measured, and the time and the logarithm of the TCE concentration divided by the initial

concentration were plotted along the horizontal and vertical axes, respectively. The first order reaction rate constant ( $\text{hr}^{-1}$ ) was calculated from the slope of the plot, and the constants are listed in Table 1. The first order reaction rate constant hardly varied  
5 within the above time intervals.

10045316 " 110701

Table 1

	Content of element in iron powder (% by mass)						Degree of precipitation of S compound	Application of finish reduction	First-order rate constant of dehalogenation of TCE (hr <sup>-1</sup> )

10045316-110701

- [0065] The iron powders in Examples 1 to 8 contain large quantities of sulfur with a large degree of precipitation on the surface. Consequently, the TCE dehalogenation rate constants in Examples 1 to 8 are large with higher dehalogenation rate constants.
- 5 An obvious degree of precipitation of sulfur of 10 or more was observed in the samples in Examples 1 to 6 containing 0.1% by mass or less of Mn with higher TCE dehalogenation rate constants. The TCE dehalogenation rate constant becomes higher as the degree of precipitation of sulfur is increased to 20, 30 and so on.
- 10 [0066] Since the iron powders in Comparative Examples 1 and 2 contain less sulfur, no precipitation of sulfur on the surface is observed with a considerably slower dehalogenation rate.
- [0067] The invention provides a method suitable for practical remediation of polluted soil, water such as groundwater and gases
- 15 such as air, and an iron powder for use in remediation, wherein the dehalogenation rate constant is remarkably and unexpectedly higher in the invention as compared with decontamination treatment by dehalogenation of the halogenated hydrocarbons using conventional iron powder, thereby remarkably enhancing
- 20 decontamination without adding harmful heavy metal components.
